

\$PEACE

Executive Summary

- Board Version -

November 2025

For many years, the House of Peace Soldiers has advanced important missions, relying on its moral credibility and a network of loyal people. However, like almost all NGOs in the world, two challenges have always been present.

The Web3 business plan has been designed precisely to address these concerns:

we want to transform the House of Peace Soldiers from a classic, campaign-dependent NGO into a “peace economy” with a transparent, on-chain treasury that finances missions every year from its own yield, without spending the principal and without having to worry each year about “where the budget will come from this time”.

To reach this goal, we have defined a three-layer infrastructure:

Layer One: Peace Companions and a Simple User Experience

In the first layer, the focus is on people: long-standing members, volunteers, supporters, and young people who are just getting to know us. Their main entry point is a Telegram MiniApp (and later wallets and other Web3 tools).

A user enters, registers, and receives a digital “Peace Passport”; a passport that is issued as a non-transferable cNFT on the Solana network and gives them an official identity inside the ecosystem. This passport shows which missions they have supported, what role they have played, and how much “peace reputation” they have accumulated over time.

In this layer, everything must be simple, understandable, and even emotional; the user sees missions, participates or donates, and feels that they are truly part of a global peace army – not just a “regular user”.

Layer Two: Mission Engine and Governance

The second layer is where missions are defined and managed. Partner NGOs and local partners submit their missions into the system; for each mission, the budget, objectives, outcome indicators, and execution timeline are specified. Then, specialist councils – such as the Treasury Council, NGO Council, and Risk/Legal Council – review and approve these missions.

When a mission is executed, its output does not remain only at the level of “reports and pictures”; it is scored using an index called HII (Human Impact Index). In other words, the human impact of the mission is converted into a number. Alongside this, the WIR (Wealth–Impact Ratio) shows how the growth of the treasury compares to the number of people and the quality of lives that have benefited from this wealth. The goal is for decision-making to be based as much as possible on real, transparent data rather than subjective judgments.

Layer Three: Treasury, \$PEACE Token, and Peace Store

In the third layer, capital is located: the on-chain treasury, the \$PEACE token, and the Peace marketplace (Peace Store).

In the mid-case scenario, we have targeted building a treasury of about 30 to 40 million USD over the coming years; not overnight, but through a combination of capital raising, operating revenues, and the treasury's own growth. The composition of this treasury is allocated between stablecoins and lower-risk assets, with a smaller portion in more volatile growth assets such as SOL, so that in an ideal case we approach around 9 to 10 percent net annual yield, without exposing the principal to excessive risk.

A significant part of this yield is allocated each year to a "Mission Pool" to finance priority missions, and another part is reinvested back into the treasury so that the capacity for future years increases. Alongside this treasury, we have Peace Store: a place where products and services are offered and part of their revenue flows back into missions – connecting the real-world economy with the digital peace economy.

Let us assume that a partner NGO in one of the priority regions proposes a mission called "Youth Reconciliation and Empowerment Program", with a hypothetical budget of 200,000 USD, clear objectives, a defined number of young beneficiaries, number of workshops, and a target rate of return to education or employment.

This mission is registered in the system, reviewed and approved from identity, financial, and operational perspectives, and its budget is released in several installments. At the same time, the mission is highlighted inside the MiniApp and in the Peace Store; people see it through their Peace Passport, engage with it, campaigns are formed around it, and micro-donations flow into it. The NGO uploads reports, documents, and photos throughout the process, and at the end, the HII engine converts all of this into a human-impact score – for example, 82 out of 100.

This score sits on the NGO's profile and on our peace map, and helps us and the community in deciding on future missions. A portion of the treasury's yield in the next year is again allocated to similar or related missions, and gradually a cycle emerges:

capital → mission → impact → credibility → more capital.

Peace Wealth Cycle and the Phased Path

This is the cycle we call the "Peace Wealth Cycle"; similar to university endowments that preserve the principal and use the yield to finance scholarships and projects year after year – with the difference that

we, in addition to financial metrics, also bring human metrics such as HII and WIR into play and say: *this amount of wealth has been spent for this number of people, with this quality of change.*

The path to reach this point is designed in four phases:

In Phase One, we build the rails: the MiniApp, Peace Passport, token, core treasury contracts, and governance.

In Phase Two, we run 3 to 5 real missions on these rails to see what works well in practice and what needs adjustment.

In Phase Three, if Phase Two is successful, we focus on growing the treasury, increasing the number of missions, and stabilizing active users so that the project moves from a “pilot” to a sustainable economic model.

And in Phase Four, once the rails and results are stabilized, we can confidently talk about global scaling and presenting Peace Soldiers as one of the leading models in PeaceFi.

Alongside this journey, comprehensive sections in the plan are dedicated to risk, governance, and legal compliance to address management concerns. The governance model is multi-layered but its complexity remains in the background; the end user only sees a few simple buttons in the MiniApp. Protective “shields” for treasury crisis conditions, backup scenarios for external services, and frameworks for dealing with unsuccessful missions have all been pre-mapped. Many parameters (such as risk tolerance and the geography of missions) are intentionally left open, to be calibrated together after the questionnaire is completed and accurate data from you and the team is received.

Ultimately, this investment round is intended to finance the first two phases: building the rails and executing the first missions. My goal as project lead is for this plan to become a real bridge between the experience and moral capital of the House of Peace Soldiers and the new tools we now have – tools that help move “peace” from episodic, campaign-based projects into a transparent, measurable economy that remains faithful to your core values.

TGE and IDO – Peace Soldiers

At the heart of this model, tokenomics, TGE, and IDO act as the financial engine of the project. Put simply, by designing the \$PEACE token and the events around it, we want to inject the initial financial fuel into the system and place it in a transparent, relatively conservative treasury – a treasury that later can finance missions from its own yield, rather than through constant token sales.

The \$PEACE token is not just a coin for trading; its key role is to ensure that the capital raised from investors and the community enters the treasury in an organized and traceable way. This treasury is kept on-chain, and the rules for distribution and use of tokens are designed so that it is clear from the very beginning which share belongs to the treasury, which to the community and growth, which to the team, and which to investors.

TGE (Token Generation Event) is the moment the token is officially born on the network. At this moment, the total token supply is defined on paper, but only a small portion is actually liquid; the rest is subject to lock-ups and gradual vesting schedules. The goal is to ensure that no one – not the team, not investors, and not even the community – can flood the market with a large volume in the short term and destabilize it.

Where the role of initial funding becomes clear is the IDO (Initial DEX Offering) – the public token sale event (under applicable regulations and via reputable launchpads or platforms). In the IDO, we offer a specific, relatively small percentage of tokens to the community, supporters, and smaller investors in a transparent structure. The funds raised from the IDO serve two main purposes:

- A major portion goes into the project’s treasury, to form the core Peace Fund which is then invested through conservative strategies to generate annual yield.
- A smaller portion is used for launch and setup costs: product development, team, technical infrastructure, launch marketing, and initial operating expenses.

In this way, the IDO is not just a “one-off token sale” for us; it is a strategic bridge to fill the treasury and build a financial backbone for the missions.

Alongside the IDO and initial capital, several other revenue streams are designed to gradually reduce our dependence on token sales. The most important of these is the treasury yield itself; the raised capital is placed into stablecoins and relatively safe assets that yield a defined percentage annually. This yield is one of the primary sources for financing missions.

Another source is the ecosystem's operational revenues: fees from Peace Store, specific services, and protocol transactions, as well as NFT and exceptional product revenues. These can directly support project development and missions while also helping reinforce the treasury.

The \$PEACE token also plays a role in governance, incentives, and access. A Peace Passport holder with a defined amount of tokens can participate in votes, receive priority in airdrops, access special parts of the marketplace or services, and in short, hold a more meaningful share in the fate of the “peace economy”. In this way, the token’s value is not only tied to its exchange price but also to the role and rights it grants its holder within the system.

In one sentence: with TGE and IDO, we inject the initial financial fuel into the system, place it inside a transparent treasury full of predefined safeguards, and then, through the treasury’s yield and side revenues such as Peace Store and protocol fees, we build a long-term financial engine for peace missions – an engine that is both understandable and quantifiable for investors, and reassuring for you as founder that the project will not turn into a “pure token game”.

Peace Soldiers DAO and Governance System

If we consider the token and treasury as the project’s financial heart, the DAO and governance system are its brain and spine. This structure ensures that money, power, and decisions stay in service of the peace mission – not the other way around.

Our goal is to build a decision-making system that combines three elements:

the experience and moral authority of the House of Peace Soldiers, the collective intelligence of the community, and the professional discipline of modern finance. We do not want to create a loose, chaotic DAO, nor a fully centralized structure like a classic organization.

At the top, there is a Foundation Board of Trustees that holds the ultimate legal responsibility and ensures that DAO decisions remain within the mission and legal obligations. Beneath that, there are specialist councils such as the Treasury Council, NGO Council, Security Council, and Legal/Risk Council. Their core function is to review and refine proposals from technical, financial, operational, and legal perspectives before these are put to a general vote. They can issue warnings, propose amendments, and in critical cases have the power to temporarily suspend actions, but they cannot, on their own, change the overall direction of the project.

The next layer is the PS-DAO itself, where voting happens. Here, each person’s vote is not only based on token balance. Every human is first recognized via their Peace Passport, and their credibility is built through real participation and HII-based impact scores. On top of that, a defined and capped amount of tokens gives extra voting weight. This means that no “whale” can simply buy influence with money, and at the same time, real peace-building activity is not left without weight and impact.

For the end user, voting must not feel complex or intimidating. Inside the MiniApp, they see proposal cards such as “Seasonal Mission Budget Proposal”, “Treasury Parameter Change”, “New Partner Onboarding”, and so on. Each card summarizes the opportunity, risk, and the user can cast a “yes”, “no”, or “abstain” vote with a few taps. Their vote is recorded both on-chain and as governance history attached to their Peace Passport.

To avoid pushing everything on-chain 100% from day one and increasing technical and legal risk, we have a three-stage governance migration plan:

In Phase Zero, we primarily practice and gather signals; decisions are made using simpler off-chain tools, with participation from core stakeholders.

In Phase One, we move to a hybrid governance model: major decisions (budget, treasury, critical upgrades) are executed and recorded on-chain, while lower-risk topics remain off-chain.

In Phase Two, once processes are stable, we move as much as feasible toward full on-chain governance with identity-based voting, Peace Passports, and token influence caps.

One of the key tools in this system is the “Adaptive Shields” mechanism – a bridge between “numbers” and “actions”. Several core indicators such as treasury runway (months of coverage), liquidity depth, token volatility, concentration of risk in a single asset, or mission quality (via HII) are monitored continuously. If these indicators are in the green zone, the project is in normal mode. If they enter the yellow zone, more conservative measures are automatically activated, such as reducing the growth rate of

mission budgets or pausing specific experiments. If indicators shift into the red zone, stricter policies kick in: temporarily stopping some missions, increasing the treasury's stablecoin share, reducing or halting buybacks, etc. The important point is that these reactions are defined in advance inside a parameter registry, not improvised emotionally at the last minute.

The reporting model is also an integral part of governance. Each quarter, financial and impact reports are published: treasury composition and performance, mission budgets, HII scores, lessons learned, and proposed adjustments. Once a year, a deeper report is issued that shows which mission types produced the best "peace per dollar", how HII and WIR evolved, and what that implies for mission and treasury policy.

Ultimately, the DAO and governance in this project are not a decorative "Web3 layer". The design philosophy is that:

The NGO and the founder bring roots and human legitimacy.

The protocol and treasury bring financial discipline and transparent data.

and the DAO brings collective intelligence and long-term accountability.

If this system is implemented correctly, difficult decisions on budget, risk, partner selection, and mission prioritization will be lifted off the shoulders of one person or a small circle and placed on a multi-layered, transparent, and auditable structure – one that respects the years of experience of the House of Peace Soldiers, speaks a language investors and international institutions can understand, and allows the community, in a responsible way, to share in the fate of the peace economy truly.
